

TREATMENT OF NEUROLOGICAL DISORDERS BY DSRNA ADMINISTRATION**FIELD OF THE INVENTION**

The present invention relates to methods of treatment neurological disorders and to a pharmaceutical composition for the treatment of chronic pain.

**BACKGROUND OF THE INVENTION**

Methods of inhibiting the expression of genes through short single-stranded oligonucleotides or oligoribonucleotides or modified oligonucleotides perfectly complementary to the target mRNA are known as "antisense". The use of antisense oligonucleotides (ASOs) as a tool to help elucidate gene function is well-described. Antisense oligonucleotides are also being evaluated as medicaments for a wide variety of diseases.

As an alternative to antisense, sequence-specific degradation of mRNAs with oligonucleotides can also be triggered by short RNA duplexes by an RNA interference (RNAi) mechanism. RNA interference is a process of sequence-specific, post-transcriptional gene silencing initiated by double-stranded RNA that is homologous in sequence to the silenced gene. The modulation of the function of a target nucleic acid by oligoribonucleotides which inhibit the expression of said target nucleic acid is generally referred to as "RNAi" or "RNA interference". Effective target-gene specific inhibition is usually achieved by short double-stranded (ds) oligoribonucleotide and with an overhang of approximately 2 nucleotides at the ends of at least 1 strand of the duplex. Such double-stranded oligoribonucleotides are known as short interfering RNAs (siRNAs) and have for instance been used as a tools to help elucidate gene function.

Great efforts are being made to develop oligonucleotides inhibiting the expression of specific target gene for therapeutic uses. One of the problems encountered is that, due to the special characteristics of oligonucleotides (such as for example high molecular weight, high amounts of negative charge, metabolic instability), delivery of free oligonucleotides to target tissues is generally much more limited in terms of the variety of disease target tissues, than for small molecule inhibitors: for instance, free oligonucleotides have low bioavailability when

- 2 -

given orally to patients, systemic delivery of oligonucleotides leads to high levels of drug concentrated in a small number of organs, for example in liver, spleen and kidney, where the distribution is dependent on the format of the oligonucleotide (Feng et al., in 2000, European Journal of Pharmaceutical Sciences 10, 179-186). Delivery of oligonucleotides to the Central Nervous System (CNS) poses particular problems due to the blood brain barrier (BBB) that free oligonucleotides cannot cross. One means to deliver oligonucleotides into the CNS is intrathecal delivery. However, the oligonucleotides need also to be efficiently internalised into target cells of the CNS in order to achieve the desired therapeutic effect. Usually, delivery reagents such as liposomes, cationic lipids, nanoparticles forming complexes are utilized in order to aid the intracellular internalization of oligonucleotides into cells of neuronal origin. However, it is of considerable economic and technical advantage in the development of drugs if the desired pharmacological effects can be achieved without the use of tissue delivery reagents. So far, the only report describing short dsRNAs entering mammalian cells without the aid of a delivery reagent show a poor effect (Milhaud, Pierre G. et al., J. Interferon Res. (1991), 11(5), 261-5). We have now surprisingly found in accordance with the present invention, that intrathecally delivered siRNAs efficiently enter CNS tissues and are efficiently internalized into cells of the CNS system. Thus, the present invention now provides for the first time a method for functional downregulation of target genes by dsRNA in the CNS *in vivo*, thereby affecting the disease phenotype, by delivering siRNA to the CNS.

## SUMMARY OF THE INVENTION

The present invention relates to a method to treat or ameliorate neurological disorders comprising intrathecal injection of an effective amount of a double stranded (ds) RNA into a subject in need, wherein said dsRNA inhibits the expression of a target gene. In a preferred embodiment the neurological disorder is selected from the group consisting of Alzheimer, Parkinson, multiple sclerosis, schizophrenia, epilepsy, depression and pain. In a more preferred embodiment, the disorder is chronic pain, preferably chronic neuropathic pain, cancer pain or osteoarthritis pain. In another preferred embodiment, the disorder is allodynia or hyperalgesia. Alternatively, the disorder is inflammatory chronic pain. In another preferred embodiment, the target gene is selected from the group consisting of purine receptors P1 or P2, Galanin R1 receptor, Vanilloid receptors 1, voltage gated calcium channel (N-type), the tetrodotoxin-resistant sodium channel Nav1.8 (PN3/SNS), TRPM8, IL-

- 3 -

24, IL-20Ralpha or IL-20Rbeta. Particularly preferred are the P2 receptors, most preferred is P<sub>2</sub>X<sub>3</sub> or P<sub>2</sub>X<sub>2</sub>. Further preferred target genes include Mob-5 or MMP7.

The subject in need is preferably mammalian. In one aspect of this invention the subject in need is rodent, preferably a rat. In a related aspect the subject in need is a monkey or a human.

In accordance with one aspect of the present invention, the amount of dsRNA that is intrathecally injected is 50µg to 1500µg, preferably more than 180µg, more preferably more than 200µg, more than 300µg or more than 400µg.

In another aspect of the present invention, the dsRNA comprises a double-stranded region of 15 to 25 nt, preferably of 19 nt. In a related aspect, the dsRNA comprises a 3' overhang on the antisense or the sense strand or both strands of at least one nucleotide, preferably 1, 2, 3 or 4 nucleotides. In a preferred embodiment, the penultimate nucleotide of the overhang is complementary to the mRNA target strand. In another preferred embodiment, the overhang contains at least one modified nucleotide, a preferred modification is a 2-MOE modification. In a further preferred embodiment, the overhang comprises at least one UU and / or dTdT group. Also preferred is an overhang comprising UUUU or consisting of UUUU. In yet a further embodiment, the dsRNA comprises at least one modified linkage, preferred is at least one phosphorothioate linkage.

Another aspect of the present invention relates to the use of dsRNA for the treatment of chronic pain. The dsRNA is preferably administered by intrathecal injection to a subject in need and inhibits the expression of a target gene. In a preferred embodiment the chronic pain is chronic neuropathic pain, in another preferred embodiment the chronic pain is selected from the group consisting of cancer pain, osteoarthritis pain, allodynia or hyperalgesia. In further preferred embodiment the targeted gene is a gene encoding a purine receptors P1 or P2, Galanin R1 receptor, Vanilloid receptors 1, voltage gated calcium channel (N-type), the tetrodotoxin-resistant sodium channel Nav1.8 (PN3/SNS), TRPM8, IL-24, IL-20Ralpha or IL-20Rbeta, most preferred is a gene encoding P<sub>2</sub>X<sub>3</sub> or P<sub>2</sub>X<sub>2</sub>. Further preferred genes include Mob-5 or MMP7.

- 4 -

Another aspect of the present invention relates to pharmaceutical compositions comprising an effective amount of dsRNA, wherein the dsRNA inhibits the expression of a target gene. These target genes are preferably overexpressed in chronic pain, preferably chronic neuropathic pain. Preferred target genes are the purine receptors P1 or P2, Galanin R1 receptor, Vanilloid receptors 1, voltage gated calcium channel (N-type), the tetrodotoxin-resistant sodium channel Nav1.8 (PN3/SNS), TRPM8, IL-24, IL-20Ralpha or IL-20Rbeta. Particularly preferred are the P2 receptors, most preferred is P<sub>2</sub>X<sub>3</sub> or P<sub>2</sub>X<sub>2</sub>. Further preferred target genes include Mob-5 or MMP7. In another preferred embodiment, the pharmaceutical composition comprising an effective amount of a double stranded RNA is selected from the group consisting of SEQ ID Nos: 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 and 16.

Other objects, features, advantages and aspects of the present invention will become apparent to those of skill from the following description. It should be understood, however, that the following description and the specific examples, while indicating preferred embodiments of the invention, are given by way of illustration only. Various changes and modifications within the spirit and scope of the disclosed invention will become readily apparent to those skilled in the art from reading the following description and from reading the other parts of the present disclosure.

#### DETAILED DESCRIPTION OF THE INVENTION

It is contemplated that the invention described herein is not limited to the particular methodology, protocols, and reagents described as these may vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments only, and is not intended to limit the scope of the present invention in any way.

Unless defined otherwise, all technical and scientific terms used herein have the same meanings as commonly understood by one of ordinary skill in the art to which this invention belongs. Although any methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, the preferred methods, devices and materials are now described. All publications mentioned herein are incorporated by reference for the purpose of describing and disclosing the materials and methodologies that are reported in the publication which might be used in connection with the invention.

In practicing the present invention, many conventional techniques in molecular biology are used. These techniques are well known and are explained in, for example, Harlow, E. and Lane, eds., 1988, "Antibodies: A Laboratory Manual", Cold Spring Harbor Press, Cold Spring Harbor, Current Protocols in Molecular Biology, Volumes I, II, and III, 1997 (F. M. Ausubel ed.); Sambrook et al., 1989, Molecular Cloning: A Laboratory Manual, Second Edition, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y.; DNA Cloning: A Practical Approach, Volumes I and II, 1985 (D. N. Glover ed.); Oligonucleotide Synthesis, 1984 (M. L. Gait ed.); Nucleic Acid Hybridization, 1985, (Hames and Higgins); Transcription and Translation, 1984 (Hames and Higgins eds.); Animal Cell Culture, 1986 (R. I. Freshney ed.); Immobilized Cells and Enzymes, 1986 (IRL Press); Perbal, 1984, A Practical Guide to Molecular Cloning; the series, Methods in Enzymology (Academic Press, Inc.); Gene Transfer Vectors for Mammalian Cells, 1987 (J. H. Miller and M. P. Calos eds., Cold Spring Harbor Laboratory); and Methods in Enzymology Vol. 154 and Vol. 155 (Wu and Grossman, and Wu, eds., respectively).

As used herein and in the appended claims, the singular forms "a", "an", and "the" include plural reference unless the context clearly dictates otherwise.

As used herein, "double-stranded ribonucleic acid (dsRNA)", as used herein, refers to an oligoribonucleotide or polyribonucleotide, modified or unmodified, and fragments or portions thereof, of genomic or synthetic origin or derived from the expression of a vector, which may be partly or fully double-stranded and which may be blunt-ended or contain a 5'- and/or 3'-overhang, and also may be of a hairpin form comprising a single oligoribonucleotide which folds back upon itself to give a double-stranded region.

As used herein "siRNA" denotes short interfering RNAs and refers to short double stranded ribonucleic acids useful for RNAi.

As used herein "inhibition" of gene expression means the reduction of the expression of said gene by at least 10%, 33%, 50%, 90%, 95% or 99%.

As used herein, the term "form" or "format" of in relation to oligonucleotides refers to different chemical nature of the oligoribonucleotide, in particular to modifications as

- 6 -

compared to naturally occurring ribonucleotides, such as for instance chemically modified 2'OH groups of the ribose moiety or the modified internucleosidic linkages such as phosphothioate linkages, or the modified nucleobases such as for example 5-methyl-C.

As used herein "Subject" refers to any human or nonhuman organism. Preferred are mammalian organisms.

As used herein the term nucleotide means ribonucleotide or deoxyribonucleotide, the terms oligonucleotide and oligoribonucleotide are interchangeable and refer, depending on the context, to modified or unmodified oligonucleotides comprising ribonucleotides and / or deoxyribonucleotides.

The present invention is based on the surprising discovery that intrathecally injected dsRNA inhibited the expression of a target gene thereby leading to a therapeutic effect in vivo, thus providing for the first time that a successful therapeutic treatment of a neurological disorder has been achieved by administration of dsRNA. Furthermore, the magnitude of the pharmacological effect from the siRNA on allodynia is much greater than that from the analogous antisense oligonucleotide. For instance, a dose limiting toxicity from use of the antisense oligonucleotide does not allow a pharmacological effect on allodynia to be observed, whereas no such dose limiting toxicity was observed from use of the siRNA, showing the possible advantages of using siRNAs over ASOs. The present invention makes therefore dsRNA available for the therapeutic treatment of neurological diseases.

In accordance with the present invention, the ribonucleic acid used for inhibition will have at least a partially double-stranded character, but may also be totally double-stranded. The RNA can be a single strand that is self-complementary or may comprise two or more separate complementary strands.

Particularly preferred in accordance with the present invention are short double-stranded RNAs, also termed siRNAs, having a length of 10 to 50 nucleotides, preferably 15 to 25 nucleotides. Yet more preferred are dsRNA's composed of oligoribonucleotides having a duplex length of 17 to 21 ribonucleotides. Even more preferred are oligoribonucleotides having a duplex length of 19 ribonucleotides.

- 7 -

The efficiency, i.e. the degree of inhibition of the target gene, is dependent on a number of different factors including the specificity of the dsRNA for its target sequence. In this context, specificity means homology, i.e. sequence identity between the dsRNA in the duplex region and the target sequence. It is understood by a person skilled in the art that 100% sequence identity is not required in order to achieve significant inhibition. Normally, at least 75% sequence identity between the dsRNA and the target sequence is sufficient in order to inhibit expression of the target nucleic acid. Preferred is a sequence identity of at least 80%, more preferred is a sequence identity of at least 90%. Most preferred is a sequence identity of at least 95% between the dsRNA and the target sequence. The best is clearly 100%. In order to target only the desired target mRNA, the siRNA reagent should have 100% homology to the target mRNA and at least 2 mismatched nucleotides to all other genes present in the cell or organism. Methods to analyze and identify ds RNAs with sufficient sequence identity in order to effectively inhibit expression of a specific target sequence are known in the art. Sequence identity may be optimized by sequence comparison and alignment algorithms known in the art (see Gribskov and Devereux, *Sequence Analysis Primer*, Stockton Press, 1991, and references cited therein) and calculating the percent difference between the nucleotide sequences by, for example, the Smith-Waterman algorithm as implemented in the BESTFIT software program using default parameters (e.g., University of Wisconsin Genetic Computing Group). Another factor affecting the efficiency of the RNAi reagent is the target region of the target mRNA. The region of a target mRNA effective for inhibition by the RNAi reagent may be determined by experimentation. Most preferred mRNA target region would be the coding region. Also preferred are untranslated regions, particularly the 3'-UTR, splice junctions. For instance, transfection assays as described in Elbashir et al. (2001) may be performed for this purpose. A number of other suitable assays and methods exist in the art which are well known to a person skilled in the art.

The dsRNA according to the present invention may also contain modified nucleotide residues. As anyone having skill in the art of drug development would readily understand, siRNAs can exist in various formats as described in Tolen et al. 2002, *Nucl. Acids Res.* 30, 1757-1766; Elbashir S.M. et al, 2001 *EMBO J.*, 20, 6877-6888; FEBS 2002, 521, 195-199; *Current Biology* 2001, 11, 1776-1780; *Nature Biotech.* 2002, 19, 497-500; *Nature Biotech.* 2002, 19, 505-508; *Nucleic Acids Research* 2002, 20, 1757-1766; *Science* 2002, 296, 5567, 550-553; *Methods* (San Diego, CA, United States) 2002, 26(2), 199-213.

The dsRNA may be blunt ended or ligated at or on at least one end with either loops composed of ribonucleotides or deoxyribonucleotides or a chemical synthetic linker (WO00/44895). In a preferred embodiment, the ribonucleic acid contains 3'-end nucleotide overhangs on the antisense strand and / or the sense strands of the dsRNA of at least one ribonucleotide or deoxyribonucleotide, or modified nucleotide. Preferred are overhangs with 1, 2, 3 or 4 nucleotides. The overhangs may contain both ribonucleotide(s) and deoxyribonucleotide(s) which in addition may contain modified sugar moieties. The overhang may be of any sequence, but in a preferred embodiment, the overhang is complementary to the target mRNA strand. In another preferred embodiment the overhang contains at least one UU group or dTdT group. In another preferred embodiment, the overhang on the antisense strand has the penultimate overhanging nucleotide complementary to the mRNA target strand. Preferably, such an overhang is a 2-nucleotides overhang. In a further preferred embodiment, the overhang is composed of 4 Us.

In another preferred embodiment, the extreme 3'-position of the siRNA is a hydroxyl group. Additionally, the 5'-end may be a hydroxyl or phosphate group.

The sugar moieties may be unmodified or modified. Preferred modified sugar moieties oligonucleotides comprise one of the following at the 2' position: F; O-, S-, or N-alkyl; O-, S-, or N-alkenyl; O-, S- or N-alkynyl; or O-alkyl-O-alkyl, wherein the alkyl, alkenyl and alkynyl may be substituted or unsubstituted C 1 to C 10 alkyl or C2 to C10 alkenyl and alkynyl. Particularly preferred are  $O[(CH_2)_n O]_m CH_3$ ,  $O(CH_2)_n OCH_3$ ,  $O(CH_2)_n NH_2$ ,  $O(CH_2)_n NR_2$ ,  $O(CH_2)_n CH_3$ ,  $O(CH_2)_n ONH_2$ , and  $O(CH_2)_n ON[(CH_2)_n CH_3]_2$ , where n and m are from 1 to about 10. Other preferred oligonucleotides comprise one of the following at the 2' position: C1 to C10 lower alkyl, substituted lower alkyl, alkaryl, aralkyl, O-alkaryl or O-aralkyl, SH, SCH<sub>3</sub>, Cl, Br, CN, CF<sub>3</sub>, OCF<sub>3</sub>, SOCH<sub>3</sub>, SO<sub>2</sub> CH<sub>3</sub>, ONO<sub>2</sub>, NO<sub>2</sub>, N<sub>3</sub>, NH<sub>2</sub>, heterocycloalkyl, heterocycloalkaryl, aminoalkylamino, polyalkylamino, substituted silyl, an RNA cleaving group, a reporter group, an intercalator, a group for improving the pharmacokinetic properties of an oligonucleotide, or a group for improving the pharmacodynamic properties of an oligonucleotide, and other substituents having similar properties. A preferred modification includes 2'-methoxyethoxy (2'-O--CH<sub>2</sub> CH<sub>2</sub> OCH<sub>3</sub>, also known as 2'-O--(2-methoxyethyl) or 2'-MOE) (Martin et al., *Helv. Chim. Acta*, 1995, 78, 486-504) i.e., an alkoxyalkoxy group. A further preferred modification includes 2'-

- 9 -

dimethylaminoxyethoxy, i.e., a  $O(CH_2)_2 ON(CH_3)_2$  group, also known as 2'-DMAOE, 2'-methoxy (2'-O-CH<sub>3</sub>), 2'-aminopropoxy (2'-OCH<sub>2</sub> CH<sub>2</sub> CH<sub>2</sub> NH<sub>2</sub>). A further preferred modification of this category is the bicyclic class of modifications known collectively as LNAs (Locked Nucleic Acids) as described in Rajwanshi et al., *Angew. Chem. Int. Ed.* 2000, 39, 1656-1659. One of skill in the art may use conventional methods to create such modified sugar structures. Representative United States patents that teach the preparation of such modified sugar structures include, but are not limited to, U.S. Pat. Nos. 4,981,957; 5,118,800; 5,700,920 and 5,969,116 each of which is incorporated by reference herein in its entirety.

The internucleoside linkage of the dsRNA may be the "normal" 3' to 5' phosphodiester linkage or contain at least one chemically modified linkage. In a preferred embodiment, the at least one overhanging nucleotide contains one or more modified linkages, whereas the double-stranded part of the oligonucleotide contains phosphodiester internucleoside linkages. Preferred modified linkages include but are not limited to, for example, those disclosed in U.S. Pat. Nos. 3,687,808; 4,469,863 and 5,625,050; each of which is incorporated by reference herein in its entirety. In a preferred embodiment the linkages are phosphorothioates, chiral phosphorothioates or phosphorodithioates. Techniques for the synthesis of compounds containing oligonucleotides with modified linkages as described above may be achieved using conventional methodologies, and are familiar to one of skill in the art.

The oligoribonucleotides may be prepared by chemical synthesis (Micura R., *Angewandte Chemie, International Edition* (2002), 41(13), 2265-2268) on commercially available or homemade oligonucleotide synthesizers using a number of different chemistries that are well known in the art. The oligonucleotide may also be prepared by in vitro transcription of a suitable template using for instance a commercially available kit such as the Silencer™ siRNA construction kit by Ambion. Alternatively, the oligoribonucleotides may be synthesized by transcription of siRNA's intracellularly from plasmids through both transient or stable transfection (Paddison PJ et al., 2002, *Genes and Development* 16, 948-958, Paul et al., 2002, *Nat. Biotech* 29, 505-508).

The effect of dsRNA on gene expression will typically result in expression of the target gene being inhibited by at least 10%, 33%, 50%, 90%, 95% or 99% when compared

- 10 -

to a cell not treated according to the present invention. Lower doses of administered material, lower concentrations of dsRNA in the cell and/or longer times after administration of dsRNA may result in inhibition at a lower level and/or in a smaller fraction of cells (e.g., at least 10%, 20%, 50%, 75%, 90%, or 95% of targeted cells). However, it is within the skill of the art to adapt conditions to provide the desired result. Quantitation of gene expression can be established by assessing the amount of the targeted gene product in the cell. For example, any mRNA transcribed from the target gene may be detected with a hybridization probe, or RT-PCR based methodologies, or translated polypeptide may be detected with an antibody raised against the encoded polypeptide.

The dsRNA is delivered in accordance with the present application by intrathecal injection (i.e. injection into the spinal fluid which bathes the brain and spinal chord tissue). Intrathecal injection of siRNA's into the spinal fluid can be performed as a bolus injection or via minipumps which can be implanted beneath the skin, providing a regular and constant delivery of siRNA into the spinal fluid. The circulation of the spinal fluid from the choroid plexus, where it is produced, down around the spinal chord and dorsal root ganglia and subsequently up past the cerebellum and over the cortex to the arachnoid granulations, where the fluid can exit the CNS, that, depending upon size, stability, and solubility of the compounds injected, molecules delivered intrathecally could hit targets throughout the entire CNS.

The amount of intrathecally injected dsRNA may vary from one target gene to another target gene and the appropriate amount that has to be applied may have to be determined individually for each target gene. Typically this amount will be in the range between 10 $\mu$ g to 2mg, preferably 50 $\mu$ g to 1500 $\mu$ g, more preferably 100 $\mu$ g to 1000 $\mu$ g. It has been found in accordance with the present invention that the dose limiting toxicity was at much lower amount of oligoribonucleotides for ASOs than for siRNA. For instance, whereas a dose limiting toxicity in the rat model was observed at 180 $\mu$ g per day for ASOs, such a dose limiting toxicity was still absent at 400 $\mu$ g per day for siRNAs. Thus, in a preferred embodiment of the present invention the dose of the intrathecally injected siRNA is at least 50 $\mu$ g, more preferably at least 100 $\mu$ g, more preferably at least 150 $\mu$ g per day, more preferably at least 180 $\mu$ g, more preferably at least 200 $\mu$ g, more preferably at least 300 $\mu$ g, most preferably at least 400 $\mu$ g. It will be apparent to a person of skill in the art that the dose

of intrathecally injected dsRNA will have to be adjusted appropriately in other organisms, the appropriate dose for humans, for instance, may be considerably higher.

In accordance with the present invention, the gene to be inhibited is expressed in the CNS. The target gene is often, but not always a gene which is misregulated, often upregulated in a given disease state. Examples for genes expressed in the CNS are genes for cytokines, genes causal for neuro-degeneration or regeneration such as Alzheimer or Parkinson or multiple sclerosis, viral genes from viruses infecting the CNS, genes causal for schizophrenia, epilepsy or depression. In a preferred embodiment the gene is causal for pain.

Pain is a term that encompasses a spectrum of clinical states. Acute pain serves as a physiological warning for a potentially tissue-damaging situation. Chronic pain occurs when the stimulus and pain are unrelated and the pain is no longer a protective mechanism. Chronic pain states are characterised by a number of clinical features. As well as spontaneous pain, patients may exhibit hyperalgesia (a greatly exaggerated response to a noxious mechanical, temperature or chemical), and allodynia (previously non-noxious stimuli are now perceived as painful). All these features result from a complex series of events involving changes in the function of sensory nerves in the periphery and in the processing of sensory information in the spinal cord and brain. These changes occur in response to direct neuronal damage or in response to mediators released during tissue damage or inflammation. Broadly speaking, chronic pain syndromes can be defined as inflammatory (also known as nociceptive) or neuropathic. Chronic inflammatory pain, as its name suggests, occurs during conditions in which there is underlying inflammation such as rheumatoid arthritis, burns, muscle damage or surgical wounds. Knowledge of the mechanisms underlying inflammatory pain has advanced considerably over recent years and it is known to involve a variety of mediators and their activation and sensitization of the peripheral terminals of sensory nerves and the consequent longer term changes in reactivity of spinal cord neurons. Chronic neuropathic pain is caused where there is a primary lesion or dysfunction of the nervous system and occurs, for example, during conditions such as trigeminal neuralgia, diabetic neuropathy, post-herpetic neuralgia, amputation or physical nerve damage. Chronic neuropathic pain results from damage to nerves by trauma, by diseases such as diabetes, herpes zoster, or late-stage cancer (see below), or by chemical injury (e.g. some anti-HIV drugs). It may also develop after amputation (including

- 12 -

mastectomy), and is involved in some low-back pain. The mechanisms of chronic neuropathic pain are poorly understood but are thought to involve spontaneous firing of sensory nerves due to the novel expression of certain classes of ion channel, sprouting of sensory fibres into different layers of the spinal cord, and changes in the expression of various neurotransmitters and receptors in the sensory nerves and spinal cord. Traditionally chronic neuropathic pain has proven to be intractable and is resistant to the standard non-steroidal and opiate analgesics. There is therefore clearly an unmet clinical need for new analgesics to treat this type of pain. Cancer pain is the most common chronic pain syndrome (with probably inflammatory and neuropathic components). It is estimated that one third of patients with advanced cancer will develop skeletal metastases, particularly in breast, prostate and lung cancer. Metastatic bone disease commonly results in bone pain that is usually located to a discrete area and is described as a deep, boring sensation that aches and burns, accompanied by episodes of stabbing discomfort. The mechanisms responsible for bone cancer pain are unknown but it probably involves structural damage, periosteal irritation and nerve entrapment. There is evidence for the disruption of normal bone metabolism and the production of inflammatory prostaglandins and cytokines. Current treatment of bone cancer pain rests with opiates but the doses required results in unacceptable side-effects and at least 20 % of patients still have uncontrolled pain. Novel, well tolerated and effective analgesics are desired to optimise the quality of life of these patients (Coleman RE (1997) *Cancer* 80; 1588-1594). Osteoarthritis pain is the most common form of chronic neuropathic pain (with probably inflammatory and neuropathic components) for which people visit general practitioners. Osteoarthritis is a chronic disease involving progressive structural changes in joint tissues, principally cartilage, synovium and subchondral bone. Typically, arthritic joints exhibit cartilage oedema and erosion, subchondral bone and synovial thickening, and formation of bony osteophytes, all contributing to a deformation of the articular surface. The principal clinical symptom of osteoarthritis is pain, although the mechanisms underlying the chronic neuropathic pain in this condition are not understood.

Thus in another embodiment of the present invention, the gene is causal for chronic pain. Genes causal for pain can be determined using for instance the animal models described hereinbelow. Furthermore, a variety of genes are known to be implicated with chronic pain. For example genes encoding a member of the Vanilloid receptors 1 (NM\_080706, NM\_080705, NM\_080705, NM\_080704), or a voltage gated calcium channel

- 13 -

(N-type), especially the alpha2 delta1 subunit a2d1 ( NM\_000722) and the a1B subunit (M94172 and M94173), or metabotropic glutamate receptor 1 (mGluR1) (Fundytus M.E. et al., British Journal of Pharmacology (2001), 132(1), 354-367) or the tetrodotoxin-resistant sodium channel Nav1.8 (PN3/SNS) (Yoshimura N. et al., Journal of Neuroscience (2001), 21(21), 8690-8696).

In a preferred embodiment of the present invention, the gene encodes a member of the family of the purine receptors P<sub>1</sub> or P<sub>2</sub> (Ralevic & Burnstock, Pharmacological Reviews 50 (1998), 413-492), preferably a member of the P<sub>2</sub>Y or P<sub>2</sub>X subclass. More preferred are the P<sub>2</sub>X<sub>3</sub> or the P<sub>2</sub>X<sub>2</sub> gene. Other examples of preferred genes include, but are not limited to Cathepsin S (NM\_004079), TrpM8 (NM\_024080), the Galanin R1 receptor (Jacoby AS et al., Genomics (1997) 45:3 496-508, NM\_012958, NM\_008082, NM\_001480) or the genes described in US Patent Application 60/369893 such as for instance IL-24 (NM\_006850), IL-20Ralpha or IL-20Rbeta (NM\_014432 and AAZ20504).

In another preferred embodiment the gene encodes a member of the Mob-5 family. The term " Mob-5" as used herein refers to Mob-5, Genbank # AAF75553 as well as the human ortholog of this protein, Interleukin 24 (Genbank # AAA91780). The human ortholog of rat Mob-5 is also known as hMDA-7 as well as "suppression of tumorigenicity 16 (Jiang,H et al., Oncogene 11, 2477-2486,1995). Included in the definition of the above genes are any and all forms of these polypeptides including, but not limited to, variants, partial forms, isoforms, precursor forms, full length polypeptides, fusion proteins or fragments of any of the above, from human or any other species. Apparent variants of Mob-5 include for instance c49a Genbank, Accession Number NM; AAB69171. Homologs of the above genes, which would be apparent to one of skill in the art, are also meant to be included in this definition. It is also contemplated that the term refers to the above genes isolated from naturally occurring sources of any species such as genomic DNA libraries as well as genetically engineered host cells comprising expression systems, or produced by chemical synthesis using, for instance, automated peptide synthesizers or a combination of such methods. Means for isolating and preparing such polypeptides are well understood in the art.

In another preferred embodiment the gene encodes MMP7 (matrilysin), a matrix metalloproteinase. The term "MMP7" refers to any and all forms of this polypeptide including, but not limited to, variants, partial forms, isoforms, precursor forms, the full length

- 14 -

polypeptide, fusion proteins containing the MMP7 sequence or fragments of any of the above, from human or any other species. The sequence of rat MMP7 may be found in Genbank, Accession Number NM\_012864. Homologs and orthologs of MMP7, which would be apparent to one of skill in the art, are meant to be included in this definition. It is also contemplated that the term refers to MMP7 isolated from naturally occurring sources of any species such as genomic DNA libraries as well as genetically engineered host cells comprising expression systems, or produced by chemical synthesis using, for instance, automated peptide synthesizers or a combination of such methods. Means for isolating and preparing such polypeptides are well understood in the art.

In a preferred embodiment the gene that is targeted is of mammalian origin, in a more preferred embodiment the gene is a rodent gene, most preferred is a rat gene. In another preferred embodiment the gene is a monkey or a human gene.

Another aspect of the present invention provides a pharmaceutical composition comprising an effective amount of a double stranded RNA inhibiting the expression of a gene causal for pain in an amount effective to treat chronic pain in a subject in need. In a preferred embodiment the gene is regulated in chronic neuropathic pain models). In a more preferred embodiment, the genes encode for a P<sub>1</sub> or P<sub>2</sub> Purine Receptor, more preferably for a receptor of the P<sub>2</sub>Y or P<sub>2</sub>X subclass. Most preferred are the P<sub>2</sub>X<sub>3</sub> or the P<sub>2</sub>X<sub>2</sub> gene. Other examples of preferred genes include, but are not limited to the Vanilloid receptors 1, voltage gated calcium channel (N-type), the tetrodotoxin-resistant sodium channel Nav1.8 (PN3/SNS), TRPM8, the Galanin R1 receptor or the genes described in US Patent Application 60/369893 such as for instance IL-24, IL-20Ralpha or IL-20Rbeta.

The pharmaceutical compositions disclosed herein useful for treating and/or ameliorating chronic pain, including chronic neuropathic pain, are to be administered to a patient at therapeutically effective doses to treat or ameliorate symptoms of such disorders. A therapeutically effective dose refers to that amount of the compound sufficient to result in amelioration of pain symptoms of chronic pain based on, for example, use of the McGill pain score (Melzack, R. Pain (1975) Sept. 1(3):277-299).

Compositions and formulations for intrathecal administration may include sterile aqueous solutions which may also contain buffers, diluents and other suitable additives such

as, but not limited to, penetration enhancers, carrier compounds and other pharmaceutically acceptable carriers or excipients.

Pharmaceutical compositions of the present invention include, but are not limited to, solutions, emulsions, and liposome-containing formulations. The pharmaceutical formulations of the present invention may be prepared according to conventional techniques well known in the pharmaceutical industry. Such techniques include the step of bringing into association the active ingredients with the pharmaceutical carrier(s) or excipient(s). In general the formulations are prepared by uniformly and intimately bringing into association the active ingredients with carriers.

The compositions of the present invention may be formulated into any of many appropriate dosage forms. The compositions of the present invention may for instance be formulated as suspensions in aqueous or mixed media. Aqueous suspensions may further contain substances which increase the viscosity of the suspension including, for example, sodium carboxymethylcellulose, sorbitol and/or dextran. The suspension may also contain stabilizers.

Pharmaceutical compositions suitable for use in the invention include compositions wherein the active ingredients are contained in an effective amount to achieve the intended purpose. The determination of an effective dose is well within the capability of those skilled in the art.

A therapeutically effective dose refers to that amount of active ingredient, i.e. double-stranded RNA in accordance with the present invention, useful to treat and/or ameliorate the pathological effects of chronic pain. Therapeutic efficacy and toxicity may be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., ED<sub>50</sub> (the dose therapeutically effective in 50% of the population) and LD<sub>50</sub> (the dose lethal to 50% of the population). The dose ratio between toxic and therapeutic effects is the therapeutic index, and it can be expressed as the ratio, LD<sub>50</sub>/ED<sub>50</sub>. Pharmaceutical compositions that exhibit large therapeutic indices are preferred. The data obtained from cell culture assays and animal studies is used in formulating a range of dosage for human use. The dosage contained in such compositions is preferably within a range of circulating concentrations that include the ED<sub>50</sub> with little or no toxicity. The dosage varies within this

- 16 -

range depending upon the dosage form employed, sensitivity of the patient, and the route of administration.

The exact dosage will be determined by the practitioner, in light of factors related to the subject that requires treatment. Dosage and administration are adjusted to provide sufficient levels of the active moiety or to maintain the desired effect. Factors that may be taken into account include the severity of the disease state, general health of the subject, age, weight, and gender of the subject, diet, time and frequency of administration, drug combination(s), reaction sensitivities, and tolerance/response to therapy. Guidance as to particular dosages and methods of delivery is provided in the literature and generally available to practitioners in the art.

Another aspect of the present invention provides the use of a double stranded RNA for the preparation of a medicament for the treatment of chronic pain. Preferably, the double stranded RNA inhibits purine receptors P1 or P2 or Galanin R1 receptor or IL-24 or IL-20Ralpha or IL-20Rbeta or MMP7, more preferably Mob-5 or P2X3 or P2X2. Said chronic pain is preferably cancer pain or osteoarthritis pain, more preferably hyperalgesia, most preferably allodynia.

The invention is further described by reference to the following examples. These examples are provided for illustration purposes and are not intended to be limiting.

## **EXAMPLES**

The following experiments are used to illustrate the invention.

### **Materials and Methods.**

#### **Synthesis of oligonucleotides targeting P2X3 or MOB-5**

##### *Antisense oligonucleotides (ASOs)*

The ASOs against P<sub>2</sub>X<sub>3</sub> and GAPDH are fully phosphorothioated 18-mers with nine nucleotides at the 3'-end modified with 2'-MOE groups and were synthesized using phosphoramidite chemistry (Eur. Pat. Appl. EP 992506 A2), HPLC-purified and characterized by electrospray mass spectrometry and capillary gel electrophoresis. For

mismatch - containing control oligonucleotides, the approximate base composition of the match oligonucleotides was maintained (Table 1).

TABLE 1. Sequences of ASOs used in in vitro experiments

	Target gene	Position in cds <sup>a</sup>	Relation to other ASOs <sup>b</sup>	Sequence <sup>c</sup>	GC content	SEQ ID
5037	rat P <sub>2</sub> X <sub>3</sub>	785-802		5'- CsTsCsCsAsTsCsCsAsgscscsgsa sgstsgsa-3'	61	1
5655	rat P <sub>2</sub> X <sub>3</sub>		4 MM to 5037	5'- CsTsAsCsAsGsCsCsAstscscsgscs gstsgsa-3'	61	2

5596	unrelated			5'-ccttaCsCsTsGsCsTsAsGscgtgc- 3'	61	4

<sup>a</sup>cds = coding sequence

<sup>b</sup>MM = mismatch(es)

Unless otherwise stated, internucleotidic linkages are phosphodiester, N= deoxyribonucleoside, n = 2'-O-(2-methoxyethyl) ribonucleoside, c = 2'-O-(2-methoxyethyl) 5-methyl cytidine, t = 2'-O-(2-methoxyethyl) 5-methyl uridine, s = phosphorothioate.

TABLE 2. Sequences of ASOs used in in vivo experiments

	Target gene	Position in cds <sup>a</sup>	Relation to other ASOs <sup>b</sup>	Sequence <sup>c</sup>	GC	SEQ ID
6798	rat P <sub>2</sub> X <sub>3</sub>	785-802		5'-ctccaTCCAGCCGagtga-3'	61	5
6799	rat P <sub>2</sub> X <sub>3</sub>		4 MM to 5037	5'-ctacaGCCATCCGcgtga-3'	61	6

All oligonucleotides are full phosphodiester 18mers; N is deoxyribonucleoside, n = 2'-O-(2-methoxyethyl) ribonucleoside, c = 2'-O-(2-methoxyethyl) 5-methyl cytidine, t = 2'-O-(2-methoxyethyl) 5-methyl uridine.

***Oligoribonucleotides (siRNA's)***

Modified synthetic oligoribonucleotides and modified antisense oligonucleotides described in this invention are prepared using standard phosphoramidite chemistry on ABI394 or Expedite/Moss Synthesizers (Applied Biosystems) for in vitro use and on OligoPilot II (Amersham Pharmacia Biotech) for in vivo purpose. Phosphoramidites are dissolved in acetonitrile at 0.05 M concentration (0.2M on Oligopilot II), coupling is made by activation of phosphoramidites by a 0.2 M solution of benzimidazolium triflate in acetonitrile. Coupling times are usually comprised between 3-6 minutes. A first capping is made using standard capping reagents. Sulfurization is made by using a 0.05 M solution of N-ethyl, N-phenyl-5-amino-1,2,4-dithiazol-3-thione for two minutes (described in EP-A-0992506). Oxidation is made by a 0.1 M iodine solution in THF/Pyridine/Water (1:1:1) for two minutes. A second capping is performed after oxidation or sulfurization. Oligonucleotide growing chains are detritylated for the next coupling by 2% dichloroacetic acid in dichloromethane or dichloroethane. After completion of the sequences the support-bound compounds are cleaved and deprotected as "Trityl-on" by a Methylamine solution (41% aqueous methylamine/33% ethanolic methylamine 1:1 v/v) at 35°C for 6 h for oligoribonucleotides and by a 32% aqueous Ammonia solution at 55°C for 16h for antisense oligonucleotides. Resulting suspensions are lyophilised to dryness. For oligoribonucleotides, 2'-O-silyl groups are removed upon treatment with 1M tetrabutylammonium fluoride 10min at 50°C and 6h at 35°C. The obtained crude solutions are directly purified by RP-HPLC. The purified detritylated compounds are analysed by Electrospray Mass spectrometry and Capillary Gel Electrophoresis and quantified by UV according to their extinction coefficient at 260 nM. The oligoribonucleotides and antisense oligonucleotides directed against rat P2X3 and MOB-5 and their controls are shown in table 3 and 4, respectively.

Table 3 – Oligoribonucleotides directed against rat P<sub>2</sub>X<sub>3</sub>.

RNAs NAS-11535 and NAS-11536, NAS-11537 and NAS-11538, are annealed together to give the siRNA's. The ASO NAS-4660 targets an unrelated gene. Unless otherwise stated, internucleotidic linkages are phosphodiester, N=ribonucleoside, dN=deoxyribonucleoside, n= 2'-O(methoxyethyl) ribonucleoside, s = phosphorothioate.

#### **Generation of a CHO cell line expressing rat-P2X3 (rP<sub>2</sub>X<sub>3</sub>-CHO)**

Chinese hamster ovary cells (CHO-K1, ATCC CCL61) were stably transfected with a complete rat P2X3 cDNA sequence in the vector pRK7 (kindly obtained from John Wood; Chen, C.C et al. (1995). Nature 377, 428-430.). To be able to select for transfected cells, vector was co-electroporated in 10x excess with pMC1neo (Stratagene) containing a Neomycin resistance gene. Cells were cultured in Minimal Essential Medium  $\alpha$  (MEM $\alpha$ ) supplemented with 10% (v/v) fetal bovine serum (FBS), 2-mM glutamine, and 10.000 IU/500 ml Penicillin/Streptomycin.

#### **Generation of a CHO cell line expressing rat-P2X3/P2X2 (rP<sub>2</sub>X<sub>3/2</sub>-CHO)**

rP2X3 insert was obtained by PCR using as template RT from total rat DRG RNA and using the oligos listed below:

P2X3-Hind-F: CGCAAAGCTTGGCTGTGAGCAGTTTCTCAGTATGAACTTG (SEQ ID No 17)

P2X3- SacI-R: CTTGAGCTCGGGAAGAGGCCCTAGTGACCAATAG (SEQ ID No 18)

Note: the underlined sequence is a HindIII restriction enzyme site added to the P2X3 complementary oligo. The SacI site in the reverse primer was not used for cloning.

The PCR product was amplified using Advantage-HF2 Polymerase with thermal cycling at 94°C for 30 s, 62°C for 60 s, and 68°C for 180 s for 6 cycles and 94°C for 30 s, and 68°C for 240 s for additional 29 cycles The PCR fragment was cloned in pGEM T-Easy

- 21 -

(Promega) and sequenced with T7 and M13 reverse primers. The clone had the same sequence as the Genbank cDNA with accession number X91167.

rP2X3 insert was cut out of pGEM T-Easy by digestion with NotI and subcloned into pcDNA5/FRT linearized with NotI and dephosphorylated.

rP2X2 was obtained by digestion with BamHI and XhoI of a clone (see above). rP2X2 was subcloned into pcDNA5/FRT-Neo cut with the same enzymes.

2.5 µg of each DNA was used to transfect CHO Flp-In cells containing two integrated FRT sites using FuGENE 6 reagent. Cells transfected with rP2X2 have been selected with Geneticin 500 µg/ml, then transfected with rP2X3 and selected with Hygromycin-B 200 µg/ml to obtain the double transfectant.

#### **Transfection of a cell line expressing rat-MOB-5**

The cell line used was RBA (ATCC number 1747). It is rat skin derived, grows extremely tightly attached in a flattened out, skin-like morphology, and naturally expresses ras and mob-5 (known to be ras-downstream).

24 hours before transfection, 2 x 10<sup>5</sup> cells in a volume of 2 ml per well were plated into 6-well plates to yield 70-80% confluency. The day of transfection, a 2fold stock transfection-solution was prepared by diluting Lipofectin® into serum-free OptiMEM (both GIBCO-BRL, Gaithersburg, MD) (formula: 3 µl Lipofectin per 100 nM desired final oligonucleotide concentration into 1ml OptiMEM) and incubating for 15 minutes at room temperature. This solution was then combined 1:1 with a 2fold ASO-solution containing twice the desired final amount of ASO in OptiMEM. After incubating the transfection mixture for 15 minutes at room temperature to form the transfection complex, 2 ml were added to each of the previously aspirated well of cells. A Lipofectin reagent-only control and a normal cell control (untreated) were also included. After incubation for 4 hours at 37°C, 500 µl 50% FBS in MEMα was added to each well to obtain a final FBS concentration of 10%. The cultures were incubated at 37°C in a humidified incubator with 5% CO<sub>2</sub> for 24 hours before mRNA was harvested.

### **Electroporation of Mammalian Cells**

CHO-rP2X2/3 cells were transfected with 0.15; 0.3; 0.6 or 1.2 nmole of ASO or siRNA duplex using standard electrotransfection ( $10^6$  cells/125  $\mu$ l in Biorad cuvette 0.4 cm, 250V, 0.3  $\mu$ F, infinite resistance). Following electroporation, samples were immediately combined with 6 ml of the culture medium. In result, corresponding final concentration of ASO or siRNA reagents were 10, 50, 100 or 200 nM. Cells were plated on uncoated 96-well plates (Costar, Cat. #3904) and incubated at 37°C for 24h or 48h, followed by RNA or protein extraction, respectively.

### **Total RNA Isolation and Assay by Quantitative Real Time PCR (Q-PCR)**

Total RNA was extracted and purified using RNeasy 96 kit (Qiagen). Primer pairs and FAM-labelled TaqMan probes for real time PCR were designed using the Primer Express v 2.0 program (ABI PRISM, PE Biosystems). For the Q-PCR reaction, 50 ng total RNA was mixed with 5' and 3' primers (10  $\mu$ M each), TaqMan probe (5  $\mu$ M), MuLV reverse

- 23 -

transcriptase (6.25 u, PE Biosystems), RNase Out RNase inhibitor (10 u, Life Technologies) and the components of the TaqMan PCR reagent kit (Eurogentec) in a total volume of 25  $\mu$ l following the TaqMan PCR reagent kit protocol (Eurogentec). Reverse transcription and real time PCR was performed in a GeneAmp Sequence Detector 5700 (PE Biosystems) as follows: 2 minutes reverse transcription at 50°C, 10 minutes denaturation at 95°C followed by 50 cycles of denaturation for 15 sec at 95°C and annealing and elongation for 1 min at 60°C. The relative quantitation of gene expression was calculated as described in the ABI PRISM 7700 user bulletin #2 (PE Biosystems).

### **Western Blotting**

Cells grown in 6-well plates were washed with PBS and lysed with a buffer containing 141 mM NaCl, 5 mM KCl, 2.5 mM Tris pH7.4, 50 nM  $\text{Na}_3\text{VO}_4$ , 0.1% (v/v) Nonidet P-40 (100%), and 0.06 g protease inhibitor per 100 ml. Lysates were centrifuged for 10 min at 14000 rpm. Solubilized proteins in the supernatant were subjected to SDS-polyacrylamide gel electrophoresis through NuPAGE™ 4-12% Bis-Tris Gels in a NOVEX™ Mini-Cell system, followed by transfer to PVDF membranes (Millipore). The filters were blocked for 1h with the blocking buffer contained in the ECF Western Blotting Kit (Amersham Pharmacia Biotech), washed several times in 1x PBS, pH 7.4 with 0.05% Tween 20, and incubated for 1h with the primary anti-P2X3-antibody (purchased from Neuromics) in a dilution 1:5000. With several washes in between, the filters were then incubated with the secondary antibody, tertiary antibody and ECF substrate from the ECF Western Blotting Kit following the manufacturer's suggestions. A quantification of the visualized bands was done with the software ImageQuant™ (Molecular Dynamics).

### **FLIPR Assay - Generation and Analysis of FLIPR Data**

FLIPR experiments were performed as follows. Briefly, cells were loaded with fluo-4 AM in presence of 2.5 mM probenidol for 30-45 min, washed twice with HBSS (Gibco) + 20mM HEPES, and transferred to the fluorescence reader (FLIPR, Molecular Devices). Drug plates were prepared at 5x the final concentration. Fluo-4 fluorescence was measured at a rate of 0.5 Hz for 3 min. Agonists were applied after 20 points baseline detection.

FLIPR sequence files were analyzed using Igor Pro (Wavemetrics). Baseline was set as the average of 20 points before drug addition, peak was detected as maximal signal in the 50 data points after drug addition. Relative change of fluorescence ( $\Delta F/F$ ) was

determined as (peak – baseline) / (baseline) values. These values were averaged, and for concentration-response analysis further analyzed by fitting a sigmoidal hill equation to the data. Data are presented as mean  $\pm$  S.E.M. or EC50 values as mean (95% confidence interval).

### **Animal Models of Chronic Pain**

In vivo animal models of chronic neuropathic pain include the following:

#### ***Seltzer Model***

In the Seltzer model (Seltzer et al. (1990) Pain 43: 205-218) rats are anaesthetised and a small incision made mid-way up one thigh (usually the left) to expose the sciatic nerve. The nerve is carefully cleared of surrounding connective tissues at a site near the trochanter just distal to the point at which the posterior biceps semitendinosus nerve branches off the common sciatic nerve. A 7-0 silk suture is inserted into the nerve with a 3/8 curved, reversed-cutting mini-needle, and tightly ligated so that the dorsal 1/3 to 1/2 of the nerve thickness is held within the ligature. The muscle and skin are closed with sutures and clips and the wound dusted with antibiotic powder. In sham animals the sciatic nerve is exposed but not ligated and the wound closed as in nonsham animals.

#### ***Chronic Constriction Injury (CCI) model***

In the CCI model (Bennett, G.J. and Xie, Y.K. Pain (1988) 33: 87-107) rats are anaesthetised and a small incision is made mid-way up one thigh (usually the left) to expose the sciatic nerve. The nerve is cleared of surrounding connective tissue and four ligatures of 4/0 chromic gut are tied loosely around the nerve with approximately 1mm between each, so that the ligatures just barely constrict the surface of the nerve. The wound is closed with sutures and clips as described above. In sham animals the sciatic nerve is exposed but not ligated and the wound closed as in nonsham animals.

#### ***Chung model***

In contrast to the Seltzer and CCI models which involves damage to peripheral nerves, the Chung model involves ligation of the spinal nerve. (Kim, S.O. and Chung, J.M. Pain (1992): 50:355-363). In this model, rats are anesthetized and placed into a prone position and an incision is made to the left of the spine at the L4-S2 level. A deep dissection through the paraspinal muscles and separation of the muscles from the spinal processes at the L4-S2 level will reveal part of the sciatic nerve as it branches to form the L4, L5 and L6

- 25 -

spinal nerves. The L6 transverse process is carefully removed with a small rongeur enabling visualisation of these spinal nerves. The L5 spinal nerve is isolated and tightly ligated with 7-0 silk suture. The wound is closed with a single muscle suture (6-0 silk) and one or two skin closure clips and dusted with antibiotic powder. In sham animals the L5 nerve is exposed as before but not ligated and the wound closed as before.

#### *Axotomy model*

The Axotomy model involves complete cut and ligation of the sciatic nerve. The nerve endings form neuromas but there is no behavioral correlate in this model as the nerve is not allowed to regenerate, and the foot is permanently denervated. (Kingery and Vallin, Pain 38, 321-32, 1989)

#### *High Sciatic Lesion model*

In this model, the sciatic nerve is punctured in the region of the iliac arch. Although there is no overt damage to the nerve, local swelling produces an increase in pressure on the nerve as it passes under the iliac arch. This model resembles conditions often seen in the clinic.

#### *Chronic inflammatory pain model*

The Complete Freund's Adjuvant -induced mechanical hyperalgesia may be used as a model of chronic inflammatory pain (Stein, C. et al. Pharmacol. Biochem. Behav. (1988) 31 :445-451). In this model, typically a male Sprague-Dawley or Wistar rat (200-250 g) receives an intraplantar injection of 25  $\mu$ l complete Freund's adjuvant into one hind paw. A marked inflammation occurs in this hind paw. Drugs are generally administered for evaluation of efficacy, 24 hours after the inflammatory insult, when mechanical hyperalgesia is considered fully established.

#### **Behavioral index**

In all chronic pain models (inflammatory and neuropathic) mechanical hyperalgesia is assessed by measuring paw withdrawal thresholds of both hindpaws to an increasing pressure stimulus using an Analgesymeter (Ugo-Basile, Milan). Mechanical allodynia is assessed by measuring withdrawal thresholds to non-noxious mechanical stimuli applied with von Frey hairs to the plantar surface of both hindpaws. Thermal hyperalgesia is assessed by measuring withdrawal latencies to a noxious thermal stimulus applied to the underside of each hindpaw. With all models, mechanical hyperalgesia and allodynia and

- 26 -

thermal hyperalgesia develop within 1 – 3 days following surgery and persist for at least 50 days. For the assays described herein, drugs may be applied before and after surgery to assess their effect on the development of hyperalgesia, particularly approximately 14 days following surgery, to determine their ability to reverse established hyperalgesia.

The percentage reversal of hyperalgesia is calculated as follows:

$$\% \text{ reversal} = \frac{\text{postdose threshold} - \text{predose threshold}}{\text{naive threshold} - \text{predose threshold}} \times 100$$

In the experiments disclosed herein, Wistar rats (male) are employed in the chronic neuropathic pain models described above. Rats weigh approximately 120-140 grams at the time of surgery. All surgery is performed under enflurane/O<sub>2</sub> inhalation anaesthesia.

In all cases the wound is closed after the procedure and the animal allowed to recover.

In all but the axotomy model, a marked mechanical and thermal hyperalgesia and allodynia develops in which there is a lowering of pain threshold and an enhanced reflex withdrawal response of the hind-paw to touch, pressure or thermal stimuli. After surgery the animals also exhibit characteristic changes to the affected paw. In the majority of animals the toes of the affected hind paw are held together and the foot turned slightly to one side; in some rats the toes are also curled under. The gait of the ligated rats varies, but limping is uncommon. Some rats are seen to raise the affected hind paw from the cage floor and to demonstrate an unusual rigid extension of the hind limb when held. The rats tend to be very sensitive to touch and may vocalise. Otherwise the general health and condition of the rats is good.

#### **Treatment of Animal Models of Chronic Pain**

Oligonucleotide reagents used in the animal models have been named as the following:

- 27 -

ASO: NAS-6798 (SEQ. ID 5), MSO: NAS-6799 (SEQ. ID 6), P2X3 RNAi: NAS-8646 and NAS-8647 (SEQ. ID 7 and 8 respectively), P2X3 RNAi missense: NAS-10104 and NAS-10105 (SEQ. ID 19 and 20 respectively).

#### Intrathecal delivery of siRNA.

dsRNA was administered intrathecally via an indwelling cannula in a buffer (100mM KA 2mM MgAc, 0.1749g HEPES free acid ( $M=238.3$ ), 0.2102g NaCl per 100ml RNase free water; pH 7.63 at 20°C with KOH). Rats were anaesthetised and an incision made in the dorsal skin just lateral to the midline and approximately 10 mm caudal to the ventral iliac spines. A sterile catheter (polyethylene PE10 tubing) was inserted via a guide cannula (20 gauge needle) and advanced 3 cm cranially in the intrathecal space approximately to the L1 level. The catheter was then connected to an osmotic mini-pump (Alzet) delivering P2X3 receptor or MOB-5 receptor siRNA, missense siRNA or saline (1  $\mu$ l / h, 7 days) which was inserted subcutaneously in the left or right flank. The incision was closed with wound clips and dusted with antibiotic powder. Experiments determined 180 as well as 220  $\mu$ g/day to have no signs of toxicity. Mechanical hyperalgesia was assessed on day 0, day 6 before administration of  $\alpha,\beta$ -methylene-ATP (Me-ATP) and 1h post Me-ATP by measuring paw withdrawal thresholds of both hindpaws to an increasing pressure stimulus using an Analgesymeter (Ugo-Basile, Milan). The cut-off was set at 250 g and the end-point taken as paw withdrawal, vocalisation or overt struggling. Each animal was tested only once, in random order. The statistical significance of mechanical hyperalgesia data obtained from the different experimental animal groups was analysed using ANOVA followed by Tukey's HSD test. 1.0  $\mu$ mol (in 10  $\mu$ l) of Me-ATP was given intraplantar (ipl) to the contralateral hindpaw on the final day of the experiment. 1.0 h post administration, paw withdrawal thresholds to mechanical hyperalgesia were measured.

#### EXAMPLE 1

##### Transfection of siRNA's into cell lines expressing rat P<sub>2</sub>X<sub>3</sub>

treatment	RNA [%] remaining	SD
OF	99	4
MM NAS-7558/7559	100	2
NAS-7556/7557	18	2
NAS-8646/8647	11	3
NAS-4882/4883	11	6
NAS-4884/4885	21	4

Efficacy of P2X<sub>3</sub> mRNA inhibition by variety of siRNA's delivered by Oligofectamine-mediated transfection of CHO-rP2X<sub>3</sub> cells. Q-PCR analysis. OF: control with Oligofectamine alone; mmNAS-7558/7559: control with mismatch; NAS-7556/7557: siRNA with optimised (as NAS-5037) sequence and noncomplementary moe/ps overhangs; NAS-8646/8647: as NAS-7556/7557 but with mRNA-complementary overhangs; NAS-4882/4883: siRNA with optimised (as NAS-5037) sequence and noncomplementary dTdT overhangs; NAS-4884/4885: siRNA with a sequence designed according to criteria described in Harborth, J. et al. (2001). J. Cell Science 114: 4557-4565.

**EXAMPLE 2**

Treatment	% P2X <sub>3</sub> protein remaining
No treatment	90
Oligofectamine alone	100
siRNA NAS-7556/7557	25
P2X <sub>3</sub> mismatch NAS-7558/7559	100
SiRNA unrelated	100

P<sub>2</sub>X<sub>3</sub> protein inhibition by the siRNA NAS-7556/7557, plotted as %. After SDS-PAGE, protein was blotted, immunodetected with anti-P<sub>2</sub>X<sub>3</sub> antibody (Neuromics), blot bands were quantified with the software ImageQuant™, and expression levels were plotted as % against control siRNA.

**EXAMPLE 3**

Treatment	% mRNA		SD	
	ASO	siRNA	ASO	siRNA
untreated	100	100	2.4	2.4
MM	71	77	3.0	5.6
10 nM	78	54	5.0	2.9
50 nM	71	34	2.4	4.1
100 nM	63	28	3.9	4.6
200 nM	44	22	5.2	8.5

Comparison of mRNA inhibition of P<sub>2</sub>X<sub>3</sub> expression at 4 doses by the siRNA NAS-8646/8647 and its antisense analogue NAS-5037. Electroporation of the CHO cell line expressing recombinant P2X<sub>3</sub> and recombinant P2X<sub>2</sub>. mRNA was measured with real-time quantitative PCR.

**EXAMPLE 4**

treatment	% mRNA		SD	
	ASO	siRNA	ASO	siRNA
untreated	100	100	4	4
MM	122	109	3	3
10 nM	108	83	3	5
50 nM	88	67	4	2
100 nM	82	43	3	2
200 nM	67	31	2	3

FLIPR functional assay. Downregulation of functional response to 10  $\mu$ M Me-ATP agonist by transfection of ASO-NAS-5037 and siRNA NAS-8646/8647 into a CHO-r P2X2/P2X3 cell line at concentrations of 10, 50, 100, and 200 nM 48h prior to agonist treatment as compared to untreated control and to mismatch controls (MSO-5655 and siRNA NAS-7557/7558).

**EXAMPLE 5**

Effect of P2X3 siRNA's on hyperalgesia in rats with agonist-induced pain

Left paw (agonist injected)	Paw threshold (g)			
	vehicle	P2X3 ASO 180 $\mu$ g	P2X3 RNAi 180 $\mu$ g	P2X3 RNAi 220 $\mu$ g
Naïve day 0	101.7 $\pm$ 2.0	103.3 $\pm$ 2.0	98.3 $\pm$ 4.1	101.7 $\pm$ 2.0
Predose day 6	100.0 $\pm$ 0.0	101.7 $\pm$ 2.0	101.7 $\pm$ 5.4	98.3 $\pm$ 2.0
1 h	58.3 $\pm$ 2.0	83.3 $\pm$ 2.0	75.0 $\pm$ 3.5	81.7 $\pm$ 7.4

The effect of P2X3 RNAi administered as an intrathecal infusion over 6 days on naïve rats on mechanical allodynia. On day 6: ipl injection of 1  $\mu$ mol Me-ATP and measurement of Von Frey thresholds of these treated rats. Vehicle: isotonic buffer, n=6/treatment group.

**EXAMPLE 6**

Effect of P2X3 siRNA's on allodynia in rats with agonist-induced pain

- 30 -

Left paw (agonist injected)	Von Frey threshold (g)			
	vehicle	P2X3 ASO 180 $\mu$ g	P2X3 RNAi 400 $\mu$ g	P2X3 RNAi missense 400 $\mu$ g
Naïve day 0	15 $\pm$ 0	12.6 $\pm$ 1.5	14.2 $\pm$ 0.8	13 $\pm$ 1.3

15 min post-dose	4.2 $\pm$ 0.9	4.4 $\pm$ 1.0	8.8 $\pm$ 1.3	3.3 $\pm$ 1.0
30 min post-dose	4.5 $\pm$ 0.8	6 $\pm$ 0.9	9.1 $\pm$ 1.3	4.7 $\pm$ 1.0
60 min post-dose	6.3 $\pm$ 0.8	6.4 $\pm$ 1.2	9.1 $\pm$ 1.3	5 $\pm$ 0.9

The effect of P2X3 RNAi administered as an intrathecal infusion over 6 days on naïve rats on mechanical allodynia. On day 6: ipl injection of 1  $\mu$ mol Me-ATP and measurement of Von Frey thresholds of these treated rats. Vehicle: isotonic buffer, n=6/treatment group.

#### EXAMPLE 7

Effects of P2X3 siRNA on mechanical hyperalgesia in rats with neuropathic pain (Seltzer model)

Day	Paw withdrawal thresholds (g)				
	Naive	Neuropathic			
	vehicle	vehicle	P2X3 RNAi missense 400 $\mu$ g	P2X3 RNAi 400 $\mu$ g	P2X3 ASO 180 $\mu$ g
0	102.5 $\pm$ 1.33	102.5 $\pm$ 1.33	104.375 $\pm$ 1.13	101.25 $\pm$ 0.81	102.5 $\pm$ 0.94
--	--	--	--	--	--
11	103.75 $\pm$ 1.57	58.12 $\pm$ 1.62	60 $\pm$ 1.64	60 $\pm$ 2.11	57.5 $\pm$ 1.63
12	101.87 $\pm$ 1.61	61.25 $\pm$ 1.57	61.25 $\pm$ 1.83	80 $\pm$ 0.94	75 $\pm$ 0.94
13	102.5 $\pm$ 1.33	62.5 $\pm$ 2.11	60 $\pm$ 1.33	81.87 $\pm$ 2.09	74.37 $\pm$ 2.40
14	103.12 $\pm$	61.87	64.37 $\pm$ 2.74	81.87 $\pm$ 1.87	76.25 $\pm$ 1.25

- 31 -

	0.91	$\pm 1.88$			
15	103.75 $\pm$ 0.81	63.75 $\pm 1.25$	64.37 $\pm$ 4.27	81.87 $\pm$ 1.61	75.62 $\pm$ 1.13
16	101.875 $\pm$ 1.62	64.37 $\pm 1.13$	65 $\pm$ 4.00	83.12 $\pm$ 0.91	73.12 $\pm$ 2.10
17	102.5 $\pm$ 1.64	61.87 $\pm 2.09$	63.12 $\pm$ 4.21	79.37 $\pm$ 1.75	71.25 $\pm$ 2.63
17.5	101.25 $\pm$ 1.56	63.75 $\pm 1.25$	62.5 $\pm$ 3.13	81.25 $\pm$ 1.25	71.87 $\pm$ 2.30

Four groups of rats were ligated on the left hind limb on day 0 and base line mechanical hyperalgesia was measured daily. An additional unligated group (naïve) was set up as control. Rats were cannulated on day 11 and infused with vehicle, RNAi, RNAi missense or ASO for a further 6 days. Paw withdrawal thresholds (left paw) were measured daily. Vehicle: isotonic buffer, n=8/treatment group.

**EXAMPLE 8**

Effects of P2X3 siRNA on mechanical allodynia in rats with neuropathic pain (Seltzer model)

Day	Von Frey thresholds (g)				
	Naive	Neuropathic			
	vehicle	vehicle	P2X3 RNAi missense 400 $\mu$ g	P2X3 RNAi 400 $\mu$ g	P2X3 ASO 180 $\mu$ g
0	13.75 $\pm$ 0.81	13.75 $\pm$ 0.81	13.75 $\pm$ 0.81	13.75 $\pm$ 0.81	15 $\pm$ 0
--	--	--	--	--	--
11	14.37 $\pm$ 0.63	3.87 $\pm$ 1.17	3.25 $\pm$ 0.84	4.37 $\pm$ 1.28	4.125 $\pm$ 1.00
12	13.75 $\pm$ 0.81	4.37 $\pm$ 1.28	3.25 $\pm$ 1.04	6.5 $\pm$ 1.05	4.5 $\pm$ 0.98
13	13.12 $\pm$ 0.91	4.75 $\pm$ 1.19	3.25 $\pm$ 0.99	8 $\pm$ 1.13	4.25 $\pm$ 1.03
14	14.37 $\pm$ 0.62	5.25 $\pm$ 0.92	3.25 $\pm$ 0.99	7.25 $\pm$ 1.19	4.25 $\pm$ 0.96

- 32 -

15	14.37 ± 0.62	4.75 ± 1.25	3.25 ± 0.75	7.75 ± 1.10	4.25 ± 0.96
16	15 ± 0	4.5 ± 0.98	4 ± 0.75	7 ± 1.06	3.5 ± 0.73
17	14.37 ± 0.62	5 ± 1	4 ± 0.75	7 ± 1	4.25 ± 0.95

Four groups of rats were ligated on the left hind limb on day 0 and base line mechanical allodynia was measured daily. An additional unligated group (naïve) was set up as control.

Rats were cannulated on day 11 and infused with vehicle, RNAi, RNAi missense or ASO for a further 6 days. Von Frey thresholds on the left paw were measured daily. Vehicle: isotonic buffer, n=8/treatment group.

#### EXAMPLE 9

Effects of MOB-5 siRNA on mechanical hyperalgesia in rats with neuropathic pain (Seltzer model)

Day	Paw withdrawal thresholds (g)			
	Naive	Neuropathic		
	vehicle	vehicle	MOB-5 RNAi missense 400 µg	MOB-5 RNAi 400 µg
0	101.4±2.4	103.1±1.3	99.4±1.1	100±1.9
—				
10	101.4±1.8	60.6±1.5	62.5±1.3	60±1.6
11	102.1±1.5	61.9±1.3	66.2±1.6	67.5±2.1
12	102.1±2.1	62.5±0.9	65.5±1.1	75±2.1
13	105±2.2	63.7±1.5	66.9±1.6	81.2±2.9
14	102.1±2.1	64.4±1.5	62.5±2.3	78.7±4.2
15	102.1±1.8	62.5±0.94	61.9±2.3	74.4±2.7
16	102.1±1.5	62.5±0.94	58.7±2.3	75±2.3

Four groups of rats were ligated on the left hind limb on day 0 and base line mechanical hyperalgesia was measured. An additional unligated group (naïve) was set up as control. Rats were cannulated on day 10 and infused with vehicle, RNAi or missense for a further 6 days. Paw withdrawal thresholds (left paw) were measured daily. Vehicle: isotonic buffer,

- 33 -

n=8/treatment group. The right paw for each group were also measured but showed no difference in paw withdrawal threshold to naïve animals.

**EXAMPLE 10**

Effects of MOB-5 siRNA on mechanical allodynia in rats with neuropathic pain (Seltzer model)

Day	Von Frey thresholds (g)			
	Naive	Neuropathic		
	vehicle	vehicle	MOB-5 RNAi missense 400 $\mu$ g	MOB-5 RNAi 400 $\mu$ g
0	14.3 $\pm$ 0.7	12 $\pm$ 1.2	11.9 $\pm$ 0.9	12.9 $\pm$ 1.0
--				
10	15 $\pm$ 0	5.9 $\pm$ 1.5	3 $\pm$ 0.6	6.1 $\pm$ 1.5
11	14.3 $\pm$ 0.7	5.5 $\pm$ 1.1	2.7 $\pm$ 0.5	5.7 $\pm$ 0.9
12	14.3 $\pm$ 0.7	4.2 $\pm$ 1.2	2.5 $\pm$ 0.5	6.2 $\pm$ 0.8
13	14.3 $\pm$ 0.7	4.2 $\pm$ 1.2	2.7 $\pm$ 0.5	5.7 $\pm$ 0.8
14	15 $\pm$ 0	4.0 $\pm$ 1.0	2.5 $\pm$ 0.3	6.7 $\pm$ 0.8
15	12.1 $\pm$ 1.0	3.7 $\pm$ 0.7	2.5 $\pm$ 0.3	6.5 $\pm$ 0.7
16	12.1 $\pm$ 1.0	4.2 $\pm$ 0.7	3.2 $\pm$ 0.6	6.7 $\pm$ 0.7

Four groups of rats were ligated on the left hind limb on day 0 and base line mechanical allodynia was measured. An additional unligated group (naïve) was set up as control. Rats were cannulated on day 10 and infused with vehicle, RNAi or missense for a further 6 days. Von Frey thresholds on the left paw were measured daily. Vehicle: isotonic buffer, n=8/treatment group. The right paw for each group were also measured but showed no difference in paw withdrawal threshold to naïve animals.
